APPENDIX A

ATSDR MINIMAL RISK LEVEL

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) [42 U.S.C. 9601 et seq.], as amended by the Super-fund Amendments and Reauthorization Act (SARA) [Pub. L. 99-4991, requires that the Agency for Toxic Substances and Disease Registry (ATSDR) develop jointly with the U.S. Environmental Protection Agency (EPA), in order of priority, a list of hazardous substances most commonly found at facilities on the CERCLA National Priorities List (NPL); prepare toxicological profiles for each substance included on the priority list of hazardous substances; and assure the initiation of a research program to fill identified data needs associated with the substances.

The toxicological profiles include an examination, summary, and interpretation of available toxicological information and epidemiologic evaluations of a hazardous substance. During the development of toxicological profiles, Minimal Risk Levels (MRLs) are derived when reliable and sufficient data exist to identify the target organ(s) of effect or the most sensitive health effect(s) for a specific duration for a given route of exposure. An MRL is an estimate of the daily human exposure to a hazardous substance that is likely to be without appreciable risk of adverse noncancer health effects over a specified duration of exposure. MRLs are based on noncancer health effects only and are not based on a consideration of cancer effects. These substance-specific estimates, which are intended to serve as screening levels, are used by ATSDR health assessors to identify contaminants and potential health effects that may be of concern at hazardous waste sites. It is important to note that MRLs are not intended to define clean-up or action levels

MRLs are derived for hazardous substances using the no-observed-adverse-effect level/uncertainty factor approach. They are below levels that might cause adverse health effects in the people most sensitive to such chemical-induced effects. MRLs are derived for acute (f-14 days), intermediate (15-364 days), and chronic (365 days and longer) durations and for the oral and inhalation routes of exposure. Currently, MRLs for the dermal route of exposure are not derived because ATSDR has not yet identified a method suitable for this route of exposure. MRLs are generally based on the most sensitive chemical-induced end point considered to be of relevance to humans. Serious health effects (such as irreparable damage to the liver or kidneys, or birth defects) are not used as a basis for establishing Ml&s. Exposure to a level above the MRL does not mean that adverse health effects will occur.

APPENDIX A

MRLs are intended only to serve as a screening tool to help public health professionals decide where to look more closely. They may also be viewed as a mechanism to identify those hazardous waste sites that are not expected to cause adverse health effects. Most MRLs contain a degree of uncertainty because of the lack of precise toxicological information on the people who might be most sensitive (e.g., infants, elderly, nutritionally or immunologically compromised) to the effects of hazardous substances. ATSDR uses a conservative (i.e., protective) approach to address this uncertainty consistent with the public health principle of prevention. Although human data are preferred, MRLs often must be based on animal studies because relevant human studies are lacking. In the absence of evidence to the contrary, ATSDR assumes that humans are more sensitive to the effects of hazardous substance than animals and that certain persons may be particularly sensitive. Thus, the resulting MRL may be as much as a hundredfold below levels that have been shown to be nontoxic in laboratory animals. Proposed MRLs undergo a rigorous review process: Health Effects/MRL Workgroup reviews within the Division of Toxicology, expert panel peer reviews, and agencywide MRL Workgroup reviews, with participation from other federal agencies and comments from the public. They are subject to change as new information becomes available concomitant with updating the toxicological profiles. Thus, MRLs in the most recent toxicological profiles supersede previously published levels. For additional information regarding MRLs, please contact the Division of Toxicology, Agency for Toxic Substances and Disease Registry, 1600 Clifton Road, Mailstop E-29, Atlanta, Georgia 30333.

APPENDIX A

MINIMAL RISK LEVEL

Chemical Name: Vinyl Chloride
CAS Number: 75-01-4
Date: October 1996
Profile Status: Update Postpublic Comment
Route: [x] Inhalation [ ] Oral
Duration: [x] Acute [ ] Intermediate [ ] Chronic
Graph Key: 26
Species: Rat

Minimal Risk Level: 0.5 [ ] mg/kg/day [xl ppm

Reference: John et al. 1977, 1981

Experimental design: CF-1 mice were exposed to vinyl chloride at concentrations of 0, 50, and 500 ppm for 7 hours/day on gestational days 6-15 (John et al. 1977, 1981). Concurrent control groups were used, one for each dose level. Control groups were sham-exposed to filtered room air. Exposure was conducted in chambers of 3.7 m3 volume under dynamic conditions. Animals were observed daily for clinical signs, and maternal body weights were determined several times during gestation. Animals were euthanized on gestational day 18 by carbon dioxide inhalation. Maternal liver weight was determined and uterine horns were examined. Fetuses were weighed, measured (crown-rump length), sexed, and subjected to gross and histopathological examinations.

Effects noted in study and corresponding doses: No adverse maternal or fetal effects were noted at 50 ppm, with the exception of a slight increase ($p < 0.05$) in crown-rump length. The increase in crownrump length was not observed at 500 ppm, and the biological significance of this effect is unknown. At the LOAEL of 500 ppm, delayed ossification ($p < 0.05$) was observed. An increase in resorptions at 500 ppm was considered to have been within historical control limits. Significant changes in percentage resorption, litter size, and fetal body weight would not have been observed at 500 ppm if comparison had been made to the other control group. There was frank maternal toxicity at 500 ppm (17% death).

Dose and end point used for MRL derivation:

[x] NOAEL 50 ppm [ ] LOAEL

Uncertaintv Factors used in MRL derivation:
[ ] 10 for use of a minimal LOAEL
[x] 10 for extrapolation from animals to humans
[x] 10 for human variability

Was a conversion used from ppm in food or water to a m&body weight dose? No.
If so, explain:

If an inhalation study in animals, list the conversion factors used in determining human eauivalent dose:
Since vinyl chloride readily reaches steady state, is rapidly metabolized and excreted, and neither it nor its metabolites are accumulated, periodicity is attained. Therefore, no adjustment for intermittent

exposure is necessary. The NOAEL was converted to a Human Equivalent Concentration (HEC) by multiplying the ratio of the partition coefficients in mice to that of humans (k&Q. Since the partition coefficient in mice is greater than that in humans, as seen in Table 2-3 of the profile, a default value of 1 is used for the ratio. In accordance with ATSDR policy, if a default value of 1 is used for the ratio, then the NOAEL is not changed and a full uncertainty factor of 10 is needed for extrapolation from animals to humans. An uncertainty factor (IJF) of 100 (10 for extrapolation from animals to humans and 10 for human variability) was applied. The acute inhalation MRL was calculated as follows: MRL = $NOAEL_{HEC}$ + UF = (50 ppm x λ_A/λ_H) ÷ (10 x 10) = (50 ppm x 1) ÷ 100 = 0.5 ppm.

Other additional studies or pertinent information which lend support to this MRL:

Delayed ossification (500 ppm, the lowest dose tested) was the only developmental effect observed in a rabbit developmental study (John et al. 1977; 1981).

APPENDIX A

Chemical Name: Vinyl Chloride
CAS Number: 75-01-4
Date: October 1996
Profile Status: Update Postpublic Comment
Route: [x] Inhalation [ ] Oral
Duration: [ ] Acute [x] Intermediate [ ] Chronic
Graph Key: 33
Species: Rat

Minimal Risk Level: 0.03 [ ] mg/kg/day [x] ppm

Reference: Bi et al. 1985

Experimental design: Groups of 75 adult male Wistar rats were exposed to 0, 10, 100, or 3,000 ppm vinyl chloride by inhalation 6 hours/day, 6 days/week for 12 months, with sacrifices at 3, 6, 12, and 18 months after initial exposure. Animals were deprived of food and water during exposure. The effluent values for the influx of vinyl chloride into the exposure chambers (10, 100, and 3,000 ppm) were 5.3, 20, and 330 mL/min, and for fresh air were 624, 132, and 87.2 mL/min, respectively. Animals were weighed once per month before and after exposure and observed for symptoms twice a day. The organs (kidney, liver, spleen, heart, and testes) of dead or euthanized animals were weighed; gross and histopathological examinations were performed on the testes, lungs, liver, heart, kidneys, spleen, and brain.

Effects noted in study and corresponding doses: Statistically significant ($p < 0.001$) increases in liverto-body weight ratio were observed at 10 ppm at 6 months exposure, and dose-response was evident at higher doses. Significant ($p < 0.05$) increases in heart- and spleen-to-body weight ratios were also noted at this dose level. At higher dose levels (100 ppm and above), decreased testicular weight was observed. Increased incidence of damage to seminiferous tubules was observed, presumably after 12 months of exposure (not specified).

Dose and end uoint used for MRL derivation:

[ ] NOAEL [x] LOAEL 10 ppm

Uncertainty Factors used in MRL derivation:

[x] 3 for use of a minimal LOAEL
[x] 10 for extrapolation from animals to humans
[x] 10 for human variability

Was a conversion used from ppm in food or water to a mg/body weight dose? No.
If so, explain:

If an inhalation study in animals, list the conversion factors used in determining human eauivalent dose:
Since vinyl chloride readily reaches steady state, is rapidly metabolized and excreted, and neither it nor its metabolites are accumulated, periodicity is attained. Therefore, no adjustment for intermittent exposure is necessary. The LOAEL was converted to a Human Equivalent Concentration (HEC) by multiplying the ratio of the partition coefftcients in rats to that of humans (X,/A,). Since the partition coefftcient in rats is greater than that in humans, as seen in Table 2-3 of the profile, a default value of

is used for the ratio. In accordance with ATSDR policy, if a default value of 1 is used for the ratio, then the LOAEL is not changed and a full uncertainty factor of 10 is needed for extrapolation from animals to humans. An uncertainty factor (UF) of 300 (3 for use of a LOAEL, 10 for extrapolation from animals to humans, and 10 for human variability) was used to calculate the MRL as follows: MRL = $LOAEL_{HEC}$ ÷ UF; MRL = 10 ppm x λ_A/λ_H ÷ (3 x 10 x 10) = 10 ppm x 1 ÷300 = 0.03 ppm.

Other additional studies or pertinent information which lend support to this MRL:

Liver enlargement and/or histopathological changes have been noted in a number of intermediateduration inhalation studies in animals (Lester et al. 1963; Schaffner 1978; Sokal et al. 1980, Torkelson et al. 1961; Wisniewska-Knypl et al. 1980). The study by Bi et al. 1985 shows these effects at a somewhat lower dosage. Additional support comes from a study citing immunostimulation in mice at 10 ppm (Sharma and Gehring 1979).

APPENDIX A

Chemical Name: Vinyl Chloride
CAS Number: 75-01-4
Date: October 1996
Profile Status: Update Postpublic Comment
Route: [ ] Inhalation [x] Oral
Duration: [ ] Acute [ ] Intermediate [x] Chronic
Graph Key: 5
Species : Rat

Minimal Risk Level: 2×10^{-5} [x] mg/kg/day [ ] ppm

Reference: Til et al. 1983, 1991

Experimental design: Groups of 100 Wistar rats of each sex (except for highest dose group, which contained 50 of each sex) were administered vinyl-chloride-monomer-enriched polyvinyl chloride powder in feed 4 hours/day for 149 weeks. Three dose groups (0.018, 0.17, and 1.7 mg/kg/day, representing the actual oral intake of vinyl chloride in feed) plus two control groups were used. Authors also calculated the exposure levels of vinyl chloride for the animal. These levels represent the oral intake minus the amount of vinyl chloride excreted in feces, which was considered to be still enclosed in PVC granular and therefore not bioavailable. Animals were observed until death or sacrifice in extremis, then organs were weighed and histopathologically examined. An uncertainty factor (UF) of 1,000 (10 for use of a LOAEL, 10 for extrapolation from animals to humans, and 10 for human variability) was used to derive the MRL: MRL = 0.018/1000 = 0.00002 mg/kg/day.

Effects noted in study and corresponding doses: Females fed 0.018 mg/kg/day displayed an increase in the number of hepatocellular basophilic foci indicating cellular alteration. This increase was also observed at the intermediate dose (0.17 mg/kg/day). At the highest dose (1.7 mg/kg/day), increased incidences of liver cell polymorphism, hepatic cysts, foci of cellular alteration, neoplastic nodules, and hepatocellular carcinomas and angiosarcoma were observed.

Dose and end point used for MRL derivation:

[ ] NOAEL [x] LOAEL 0.018 mg/kg/day

Uncertainty Factors used in MRL derivation:

[x] 10 for use of a LOAEL
[x] 10 for extrapolation from animals to humans
[x] 10 for human variability

Was a conversion used from ppm in food or water to a mg/body weight dose? No.
If so, explain:

If an inhalation study in animals, list the conversion factors used in determining human equivalent dose:
N/A

Other additional studies or nertinent information which lend support to this MRL:

This MRL is reinforced by a study by Feron et al. (1981) in which rats were fed diets containing PVC powder. Increased areas of cellular alteration (consisting of clear foci, basophilic foci, and eosinophilic foci) were observed in the liver of rats at an oral intake of vinyl chloride monomer of 1.8 mg/kg/day.

APPENDIX B

USER'S GUIDE

Chapter 1

Public Health Statement

This chapter of the profile is a health effects summary written in non-technical language. Its intended audience is the general public especially people living in the vicinity of a hazardous waste site or chemical release. If the Public Health Statement were removed from the rest of the document, it would still communicate to the lay public essential information about the chemical.

The major headings in the Public Health Statement are useful to find specific topics of concern. The topics are written in a question and answer format. The answer to each question includes a sentence that will direct the reader to chapters in the profile that will provide more information on the given topic.

Chapter 2

Tables and Figures for Levels of Significant Exposure (LSE)

Tables (2-1, 2-2, and 2-3) and figures (2-l and 2-2) are used to summarize health effects and illustrate graphically levels of exposure associated with those effects. These levels cover health effects observed at increasing dose concentrations and durations, differences in response by species, minimal risk levels (MRLs) to humans for noncancer end points, and EPA's estimated range associated with an upperbound individual lifetime cancer risk of 1 in 10,000 to 1 in l0,000,000. Use the LSE tables and figures for a quick review of the health effects and to locate data for a specific exposure scenario. The LSE tables and figures should always be used in conjunction with the text. All entries in these tables and figures represent studies that provide reliable, quantitative estimates of No-Observed-Adverse- Effect Levels (NOAELs), Lowest-Observed-Adverse-Effect Levels (LOAELs), or Cancer Effect Levels (CELs).

The legends presented below demonstrate the application of these tables and figures. Representative examples of LSE Table 2-l and Figure 2-l are shown. The numbers in the left column of the legends correspond to the numbers in the example table and figure.

LEGEND

See LSE Table 2-l

(1) Route of Exposure One of the first considerations when reviewing the toxicity of a substance using these tables and figures should be the relevant and appropriate route of exposure. When sufficient data exists, three LSE tables and two LSE figures are presented in the document. The three LSE tables present data on the three principal routes of exposure, i.e., inhalation, oral, and dermal (LSE Table 2-1, 2-2, and 2-3, respectively). LSE figures are limited to the inhalation (LSE Figure 2-l) and oral (LSE Figure 2-2) routes. Not all substances will have data on each route of exposure and will not therefore have all five of the tables and figures.

(2) Exposure Period Three exposure periods - acute (less than 15 days), intermediate (15-364 days), and chronic (365 days or more) are presented within each relevant route of exposure. In this

example, an inhalation study of intermediate exposure duration is reported. For quick reference to health effects occurring from a known length of exposure, locate the applicable exposure period within the LSE table and figure.

(3) Health Effect The major categories of health effects included in LSE tables and figures are death, systemic, immunological, neurological, developmental, reproductive, and cancer. NOAELs and LOAELs can be reported in the tables and figures for all effects but cancer. Systemic effects are further defined in the "System" column of the LSE table (see key number 18).

(4) Key to Figure Each key number in the LSE table links study information to one or more data points using the same key number in the corresponding LSE figure. In this example, the study represented by key number 18 has been used to derive a NOAEL and a Less Serious LOAEL (also see the 2 "18r" data points in Figure 2-1).

(5) Species The test species, whether animal or human, are identified in this column. Section 2.5, "Relevance to Public Health," covers the relevance of animal data to human toxicity and Section 2.3, "Toxicokinetics," contains any available information on comparative toxicokinetics. Although NOAELs and LOAELs are species specific, the levels are extrapolated to equivalent human doses to derive an MRL.

(6) Exposure Frequency/Duration The duration of the study and the weekly and daily exposure regimen are provided in this column. This permits comparison of NOAELs and LOAELs from different studies. In this case (key number 18), rats were exposed to 1,1,2,2-tetrachloroethane via inhalation for 6 hours per day, 5 days per week, for 3 weeks. For a more complete review of the dosing regimen refer to the appropriate sections of the text or the original reference paper, i.e., Nitschke et al. 1981.

(7) System This column further defines the systemic effects. These systems include: respiratory, cardiovascular, gastrointestinal, hematological, musculoskeletal, hepatic, renal, and dermal/ocular. "Other" refers to any systemic effect (e.g., a decrease in body weight) not covered in these systems. In the example of key number 18, 1 systemic effect (respiratory) was investigated.

(8) NOAEL A No-Observed-Adverse-Effect Level (NOAEL) is the highest exposure level at which no harmful effects were seen in the organ system studied. Key number 18 reports a NOAEL of 3 ppm for the respiratory system which was used to derive an intermediate exposure, inhalation MRL of 0.005 ppm (see footnote "b").

(9) LOAEL A Lowest-Observed-Adverse-Effect Level (LOAEL) is the lowest dose used in the study that caused a harmful health effect. LOAELs have been classified into "Less Serious" and "Serious" effects. These distinctions help readers identify the levels of exposure at which adverse health effects first appear and the gradation of effects with increasing dose. A brief description of the specific endpoint used to quantify the adverse effect accompanies the LOAEL. The respiratory effect reported in key number 18 (hyperplasia) is a Less serious LOAEL of 10 ppm. MRLs are not derived from Serious LOAELs.

(10) Reference The complete reference citation is given in chapter 8 of the profile.

(11) CEL A Cancer Effect Level (CEL) is the lowest exposure level associated with the onset of carcinogenesis in experimental or epidemiologic studies. CELs are always considered serious

effects. The LSE tables and figures do not contain NOAELs for cancer, but the text may report doses not causing measurable cancer increases.

(12) Footnotes Explanations of abbreviations or reference notes for data in the LSE tables are found in the footnotes. Footnote "b" indicates the NOAEL of 3 ppm in key number 18 was used to derive an MRL of 0.005 ppm.

LEGEND

See Figure 2-1

LSE figures graphically illustrate the data presented in the corresponding LSE tables. Figures help the reader quickly compare health effects according to exposure concentrations for particular exposure periods.

(13) Exposure Period The same exposure periods appear as in the LSE table. In this example, health effects observed within the intermediate and chronic exposure periods are illustrated.

(14) Health Effect These are the categories of health effects for which reliable quantitative data exists. The same health effects appear in the LSE table.

(15) Levels of Exposure concentrations or doses for each health effect in the LSE tables are graphically displayed in the LSE figures. Exposure concentration or dose is measured on the log scale "y" axis. Inhalation exposure is reported in mg/m^3 or ppm and oral exposure is reported in mglkglday.

(16) NOAEL In this example, 18r NOAEL is the critical endpoint for which an intermediate inhalation exposure MRL is based. As you can see from the LSE figure key, the open-circle symbol indicates to a NOAEL for the test species-rat. The key number 18 corresponds to the entry in the LSE table. The dashed descending arrow indicates the extrapolation from the exposure level of 3 ppm (see entry 18 in the Table) to the MRL of 0.005 ppm (see footnote "b" in the LSE table). a Key number 38r is 1 of 3 studies for which Cancer Effect Levels were derived. The diamond symbol refers to a Cancer Effect Level for the test species-mouse. The number 38 corresponds to the entry in the LSE table.

(18) Estimated Upper-Bound Human Cancer Risk Levels This is the range associated with the upper-bound for lifetime cancer risk of 1 in 10,000 to 1 in 10,000,000. These risk levels are derived from the EPA's Human Health Assessment Group's upper-bound estimates of the slope of the cancer dose response curve at low dose levels (q_1*)

(19) Key to LSE Figure The Key explains the abbreviations and symbols used in the figure.

APPENDIX B

Chapter 2 (Section 2.5)

Relevance to Public Health

The Relevance to Public Health section provides a health effects summary based on evaluations of existing toxicologic, epidemiologic, and toxicokinetic information. This summary is designed to present interpretive, weight-of-evidence discussions for human health end points by addressing the following questions.

1. What effects are known to occur in humans?

2 . What effects observed in animals are likely to be of concern to humans?

3 . What exposure conditions are likely to be of concern to humans, especially around hazardous waste sites?

The section covers end points in the same order they appear within the Discussion of Health Effects by Route of Exposure section, by route (inhalation, oral, dermal) and within route by effect. Human data are presented first, then animal data. Both are organized by duration (acute, intermediate, chronic). In vitro data and data from parenteral routes (intramuscular, intravenous, subcutaneous, etc.) are also considered in this section. If data are located in the scientific literature, a table of genotoxicity information is included.

The carcinogenic potential of the profiled substance is qualitatively evaluated, when appropriate, using existing toxicokinetic, genotoxic, and carcinogenic data. ATSDR does not currently assess cancer potency or perform cancer risk assessments. Minimal risk levels (MRLs) for noncancer end points (if derived) and the end points from which they were **derived are** indicated and discussed.

Limitations to existing scientific literature that prevent a satisfactory evaluation of the relevance to public health are identified in the Data Needs section.

Interpretation of Minimal Risk Levels

Where sufficient toxicologic information is available, we have derived minimal risk levels (MRLs) for inhalation and oral routes of entry at each duration of exposure (acute, intermediate, and chronic). These MRLs are not meant to support regulatory action; but to acquaint health professionals with exposure levels at which adverse health effects are not expected to occur in humans. They should help physicians and public health officials determine the safety of a community living near a chemical emission, given the concentration of a contaminant in air or the estimated daily dose in water. MRLs are based largely on toxicological studies in animals and on reports of human occupational exposure.

MRL users should be familiar with the toxicologic information on which the number is based. Chapter 2.5, “Relevance to Public Health,” contains basic information known about the substance. Other sections such as 2.7, “Interactions with Other Substances,” and 2.8, “Populations that are Unusually Susceptible” provide important supplemental information.

MRL users should also understand the MRL derivation methodology. MRLs are derived using a modified version of the risk assessment methodology the Environmental Protection Agency (EPA) provides (Barnes and Dourson 1988) to determine reference doses for lifetime exposure (RfDs).

To derive an MRL, ATSDR generally selects the most sensitive endpoint which, in its best judgement, represents the most sensitive human health effect for a given exposure route and duration. ATSDR cannot make this judgement or derive an MRL unless information (quantitative or qualitative) is available for all potential systemic, neurological, and developmental effects. If this information and reliable quantitative data on the chosen endpoint are available, ATSDR derives an MRL using the most sensitive species (when information from multiple species is available) with the highest NOAEL that does not exceed any adverse effect levels. When a NOAEL is not available, a lowest-observed-adverseeffect level (LOAEL) can be used to derive an MRL, and an uncertainty factor (UF) of 10 must be employed. Additional uncertainty factors of 10 must be used both for human variability to protect sensitive subpopulations (people who are most susceptible to the health effects caused by the substance) and for interspecies variability (extrapolation from animals to humans). In deriving an MRL, these individual uncertainty factors are multiplied together. The product is then divided into the inhalation concentration or oral dosage selected from the study. Uncertainty factors used in developing a substance-specific MRL are provided in the footnotes of the LSE Tables.
